1. For  $f \in \mathcal{C}^1(E, \mathbb{R}^n)$  with  $E$  is open subset of  $\mathbb{R}^n$  and  $Jf(x_0) \neq 0$  for some  $x_0 \in E$  and  $y_0 = f(x_0)$ . Then, let  $h(x, y) = f(x) - y \in \mathcal{C}^1(E \times \mathbb{R}^n \rightarrow \mathbb{R}^n)$  and  $h(x_0, y_0) = f(x_0) - y_0 = y_0 - y_0 = 0$ . We also can get  $\frac{\partial h}{\partial x} = Df$ . Then, by Implicit Function Theorem, there exists open sets  $U \subseteq E \times \mathbb{R}^n$  and  $W \subseteq \mathbb{R}^n$  with  $(x_0, y_0) \in U$  and  $y_0 \in W$ , and unique  $g \in \mathcal{C}^1(W, \mathbb{R}^n)$  with  $g(y_0) = x_0$  s.t.  $0 = h(g(y), y) = f(g(y)) - y \implies y = f(g(y))$  for all  $y \in W$  and  $g$  is locally inverse function of  $f$ . And we can get  $[Df^{-1}(y)] = [Dg(y)] = -[Df(g(y))]^{-1}[Dg(y)]_y = [Df(g(y))]^{-1} = [Df(f^{-1}(y))]^{-1}$  by Implicit Function Theorem, too.
2. Suppose  $f \in \mathcal{C}^1(\mathbb{R}^2, \mathbb{R})$ ,  $Df(x_0, y_0) \neq 0$  for some  $x_0, y_0$  (or  $f$  is constant function and not one-to-one). Then, suppose  $\frac{\partial f}{\partial x} \neq 0$  for neighborhood of  $(x_0, y_0)$ , and let  $h(x, y) = f(x, y) - f(x_0, y_0)$  with  $\frac{\partial h}{\partial x} \neq 0$ . by Implicit Function Theorem, there is a neighborhood  $U \subseteq \mathbb{R}^2$  and  $W \subseteq \mathbb{R}$  s.t.  $(x_0, y_0) \in U$  and  $y_0 \in W$  and a function  $g : W \rightarrow \mathbb{R}^2$  s.t.  $h(g(y), y) = f(g(y), y) - f(x_0, y_0) = 0$ . Then,  $f(g(y), y) = f(x_0, y_0)$  for  $y \in W$  and  $f$  is not one-to-one. If  $\frac{\partial f}{\partial x} = 0$ , then  $\frac{\partial f}{\partial y} \neq 0$  and use the same argument can get the same result.
3. (a)  $\nabla f(x, y, z) = (y, x, 0)$  And  $\nabla g_1(x, y, z) = (2x, 2y, 2z)$ ,  $\nabla g_2(x, y, z) = (1, 1, 1)$ .

Then, we have

$$\begin{cases} y &= 2\lambda_1 x + \lambda_2 \\ x &= 2\lambda_1 y + \lambda_2 \\ 0 &= 2\lambda_1 z + \lambda_2 \\ 1 &= x^2 + y^2 + z^2 \\ 0 &= x + y + z \end{cases}$$
