- 1. (a) If $x \in A$, d(x,A) = ||x x|| = 0 and d(x,B) = k > 0, $\phi(x) = \frac{0}{0+k} = 0$. If $x \in B$, d(x,A) = l > 0 and d(x,B) = 0, $\phi(x) = \frac{l}{l+0} = 1$. If $x \notin A \land x \notin B$, d(x,A) = l and d(x,B) = k, $\phi(x) = \frac{l}{l+k} < 1$ and is positive.
 - And for $x,y \in A$ and $\varepsilon > 0$, if $||x-y|| < \delta = \varepsilon$, $|d(x,A) d(x,Y)| < \delta = \varepsilon$. Thus, d(x,A) is continuous. Using the same way, d(x,B) is also continuous. Since $\phi(x) = \frac{d(x,A)}{d(x,A) + d(x,B)}$ is a continuous function divided by a continuous function which is greater than 0, $\phi(x)$ is also continuous.
 - (b) Let $\phi(x) = (b-a)\frac{d(x,A)}{d(x,A) + d(x,B)} + a$. From (a), we can get continuous function $\phi(x \in A) = (b-a) \cdot 0 + a = a$, $\phi(x \in B) = (b-a) \cdot 1 + a = b$, and $a \le \phi(x) \le b$ for all $x \in A$.
- 2. If f has more than one fixed point, there exists $x,y \in S$ s.t. $d(f^n(x),f^n(y))=d(x,y)$ for all $n \in \mathbb{N}$ (contradiction to $a_n \to 0$). Then, we want to show that f has fixed point. For any $x_0 \in S$, we let $x_k = f^k(x)$ and we can find a $N \in \mathbb{N}$ s.t. $a_n \le \alpha < 1$ for all n > N. Then, $d(x_{n+k},x_n) \le \alpha^{n-N}d(x_{N+k},x_N) < \alpha^{n-N} \cdot a_N d(x_k,x_0)$ for any k and n > N. Thus, $x_n \to x^* \in S$ by S is complete, and x^* is a fixed point of f.
- 3. Since $T(u)(t) = \int_a^t u(s) \ ds$, $(T^m(u)(t))' = \left(T(T^{m-1}(u))(t)\right)' = \left(\int_a^t T^{m-1}(u)(s)ds\right)' = T^{m-1}(u)(t)$

by FTC. And since $T^m(u)(a) = 0$ for all $m \in \mathbb{N}$, we can get

$$T^{m}(u)(t) = T(T^{m-1}(u))(t)$$

$$= \int_{a}^{t} T^{m-1}(u)(s) ds$$

$$= -\int_{a}^{t} T^{m-1}(u)(s) d(t-s)$$

$$= -(t-s)T^{m-1}(u)(s) \Big|_{a}^{t} + \int_{a}^{t} (t-s) d(T^{m-1}(u)(s))$$

$$= \int_{a}^{t} (t-s)T^{m-1}(u)(s)$$

$$= \int_{a}^{t} T^{m-1}(u)(s) d(\frac{-(t-s)^{2}}{2})$$

$$= \int_{a}^{t} \frac{(t-s)^{2}}{2!} T^{m-2}(u)(s) ds$$

$$\vdots$$

$$= \int_{a}^{t} \frac{(t-s)^{m-1}}{(m-1)!} d(T(u)(s))$$

$$= \int_{a}^{t} \frac{(t-s)^{m-1}}{(m-1)!} u(s) ds$$

Thus, $T^m(u) = \frac{1}{(m-1)!} \int_a^t (t-s)^{m-1} u(s) ds \le \int_a^t \frac{(t-s)^{m-1}}{(m-1)!} M \ ds \le \int_a^t \frac{M \cdot (t-a)^{m-1}}{(m-1)!} \ ds$ with M is upper bound of u. Then, taking $a_n = \frac{(t-a)^n}{(n-1)!} M$. Therefore, by 2., T has unique fixed point, and T(0) = 0 trivially.

4. We want to proof $T(f)(x) = \int_0^x f(t) dt$ has unique fixed point. Since f is on [0,1], $T(|f|)(x) \le |f(x)|$ for all f and $x \in [0,1]$. Thus, by 3., T has unique fixed point and T(0) = 0. Therefore, $\int_0^1 f(x)x^n dx = (n-1)!T^n(f)(1) = 0$ for all x implies that f(x) = 0 in [0,1].
