1. (a) Since E is Jordan region, E is bounded and for all $\varepsilon^* > 0$, we can find a grid g s.t. $\mathrm{Vol}(\partial E, g) < \varepsilon^*$.

   If $x \in \partial \mathrm{int}(E)$, $D(x, \varepsilon) \cap \mathrm{int}(E) \neq \emptyset$ and $D(x, \varepsilon) \cap (M \setminus \mathrm{int}(E)) \neq \emptyset$. Thus, $D(x, \varepsilon) \cap E \neq \emptyset$ and

   $D(x, \varepsilon) \cap (M \setminus \mathrm{int}(E)) \neq \emptyset$.

   If $D(x, \varepsilon) \cap (M \setminus E) \neq \emptyset$, then $x \in \partial E$. If $D(x, \varepsilon) \cap (M \setminus E) = \emptyset$, $D(x, \varepsilon) \subseteq E$. Then, $D(x, \varepsilon) \cap (E \setminus$

   $\mathrm{int}(E)) \neq \emptyset$, that is, $D(x, \varepsilon) \cap \partial E \neq \emptyset$. If $x \in \mathrm{int}(E)$, then exists $\varepsilon > 0$ s.t. $D(x, \varepsilon) \subseteq \mathrm{int}(E) \cap \partial E =$

   $\emptyset$. Thus, $x \in \partial E$.

   Therefore, $x \in \partial \mathrm{int}(E) \implies x \in \partial E$. Then, $\mathrm{Vol}(\partial \mathrm{int}(E)) \leq \mathrm{Vol}(\partial E) = 0$.

   And for $\mathrm{cl}(E)$, we can use the same argument to proof $D(x, r) \setminus \mathrm{cl}(E)$ is Jordan region for some

   $U \supseteq \mathrm{cl}(E)$ is open and bounded, and that implies $\mathrm{cl}(E)$ is Jordan region.

   (b) Since $\mathrm{cl}(E) = \mathrm{int}(E) \cup \partial E$ and $\mathrm{int}(E) \subseteq E \subseteq \mathrm{cl}(E)$,

   $\mathrm{Vol}(\mathrm{cl}(E)) \leq \mathrm{Vol}(\mathrm{int}(E)) + \mathrm{Vol}(\partial E) = \mathrm{Vol}(\mathrm{int}(E)) \leq \mathrm{Vol}(E) \leq \mathrm{Vol}(\mathrm{cl}(E))$.

   Therefore, $\mathrm{Vol}(\mathrm{cl}(E)) = \mathrm{Vol}(\mathrm{int}(E)) = E$.

   (c)

   $(\implies)$ From (b), we know $\mathrm{Vol}(\mathrm{int}(E)) = \mathrm{Vol}(E) > 0$, then we can find a set of rectangles R_n s.t.

   $\sum |R_n| > 0$ and $\cup R_n \subseteq \mathrm{int}(E)$. Therefore, $\mathrm{int}(E) \neq \emptyset$.

   $(\impliedby)$ Since $\mathrm{int}(E)$ is non-empty, for any $x_0 \in \mathrm{int}(E)$, there exists $\varepsilon > 0$ s.t. $D(x_0, \varepsilon) \subseteq \mathrm{int}(E)$. Then,

   we can find a small rectangle R with each length is $\dfrac{\varepsilon}{2}$ and R is contained in $D(x_0, \varepsilon)$. Thus,

   $\mathrm{Vol}(\mathrm{int}(E)) > \left(\dfrac{\varepsilon}{2}\right)^2 > 0$.

(d) Since f is continuous, for any $x_0 \in [a,b]$, we can find a sequence $x_k \to x_0$ s.t. $f(x_k) \to f(x_0)$. That

is, $A = \{(x, f(x)) \mid x \in [a,b]\}$ is closed. And since $\partial A \subseteq A$, $\mathrm{Vol}(\partial A) \le \mathrm{Vol}(A)$.

Since f is continuous on $[a,b]$ is compact, for all $\varepsilon > 0$, we can find $\delta > 0$ s.t. $|x - y| < \delta$ implies

That $|f(x) - f(y)| < \dfrac{\varepsilon}{b-a}$. Then, we can find a finite increasing sequence $\{x_i \mid x_i \in [a,b]\}_{i=1}^{N}$ s.t.

$[a,b] \subseteq D(x_i, \dfrac{\delta}{2})$. Therefore, for any $y = f(x)$, $y \in D(f(x_i), \dfrac{\varepsilon}{b-a})$ for some i.

Then, take $u_0 = a$, $u_i \in D(x_i, \dfrac{\delta}{2}) \cap D(x_{i+1}, \dfrac{\delta}{2})$, $u_N = b$, and we can get $[a,b] = \cup[u_i, u_{i+1}]$. Thus,

$A \subseteq \displaystyle\bigcup_{i=0}^{N}[u_i, u_{i+1}] \times D(\xi_i, \dfrac{\varepsilon}{b-a})$ for some $\xi_i \in \{f(x) \mid x \in [u_i, u_i = 1]\}$ with the sum of the rectangles

is $\dfrac{\varepsilon}{b-a} \cdot (b-a) = \varepsilon$. Hence, $\mathrm{Vol}(A) = 0$ and $\mathrm{Vol}(\partial A) = 0$.

(e) Yes. Since f is integrable, for any $\varepsilon > 0$, we can find an partition P s.t. $|U(f,P) - L(f,P)| < \varepsilon$.

That is, $\displaystyle\sum_{i=0}^{N} (\sup_{x \in [x_i, x_{i+1}]} \{f(x)\} - \inf_{x \in [x_i, x_{i+1}]} \{f(x)\}) \cdot (x_{i+1} - x_i) < \varepsilon$, and each one of the summation is

a rectangle that contains all $(x, f(x))$ in the intevral. Thus, $\mathrm{Vol}(A) = 0$ and $\mathrm{Vol}(\partial A) = 0$.

2. (a) For $x \in \partial(E_1 \cap E_2)$, $x \in \mathrm{cl}(E_1 \cap E_2) \cap \mathrm{cl}(M \setminus E_1 \cap E_2)$. Then, if $E_1 \cap E_2$ is not Jordan region,

$\mathrm{Vol}(E_1 \cap E_2) = a > 0$.

(b) Since E_1, E_2 are non-overlapping, $E_1 \cap E_2 \subseteq \partial E_1 \cap \partial E_2$. And since E_1, E_2 are Jordan regions,

$\mathrm{Vol}(E_1) = \mathrm{Vol}(\mathrm{int}(E_1))$ and $\mathrm{Vol}(E_2) = \mathrm{Vol}(\mathrm{int}(E_2))$. Also we have $\mathrm{int}(E_1) \cup \mathrm{int}(E_2) \subseteq E_1 \cup E_2$

and $\mathrm{int}(E_1) \cap \mathrm{int}(E_2) = \emptyset$.

$$\mathrm{Vol}(E_1) + \mathrm{Vol}(E_2) = \mathrm{Vol}(\mathrm{int}(E_1)) + \mathrm{Vol}(\mathrm{int}(E_1))$$
$$= \mathrm{Vol}(\mathrm{int}(E_1) \cup \mathrm{int}(E_2))$$
$$\le \mathrm{Vol}(E_1 \cap E_2)$$
$$\le$$

(c)
